Introduction

1.1 GAP Jupyter Kernel

This package provides a so-called kernel for the Jupyter interactive document system. This kernel is implemented in GAP.

1.2 Installation

This package requires Jupyter to be installed on your system, which on most Python installations can be achieved by issuing the following command.

`> pip install --user notebook`

Further instructions can be found at https://jupyter.org/install. This package requires the GAP packages IO, uuid, ZeroMQInterface, crypting, and json, all of which are distributed with GAP, and some of which require compilation. To compile ZeroMQInterface you need to install ZeroMQ, for details please refer to the ZeroMQInterface manual. JupyterKernel itself does not contain any kernel code that needs to be compiled. It is necessary to register JupyterKernel with your Jupyter installation. Registering the GAP jupyter kernel system-wide works as follows:

`> python setup.py install`

or registering for your user only

`> python setup.py install --user`

If GAP is not in your PATH, then you have to set the environment variable JUPYTER_GAP_EXECUTABLE to point to your GAP executable for Jupyter to be able to execute GAP, and the script jupyter-kernel-gap that is distributed with this package in the directory bin/ needs to be in your path. To start Jupyter run:

`> jupyter notebook`

Then JupyterKernel should show up in your Jupyter installation as "GAP 4".
1.3 How it works

1.3.1 Kernel Startup

This section gives a short explanation how the process of executing GAP as a kernel by Jupyter works to help with debugging issues. Jupyter registers kernels using json files in various directories. You can list which kernel specifications are installed by executing the following command:

```
> jupyter kernelspec list
```

Example:

```
Available kernels:
  python2  /usr/local/lib/python2.7/site-packages/ipykernel/resources
  gap-native /usr/local/share/jupyter/kernels/gap-native
```

If there is no line containing the `gap-native` kernel, something went wrong with `setup.py`. You can try to manually install the file `kernel.json` which is in the `etc` directory of the JupyterKernel package by copying it. Better yet, you should report this issue on the issue tracker giving which operating system you are using, your version of Jupyter and GAP, and which commands you tried to execute. What happens when Jupyter wants to start a GAP kernel is that it tries to execute the small script `jupyter-kernel-gap` (which is distributed with the JupyterKernel package), which in turn executes GAP, loading the package and then running the kernel. This script currently has to be in your `PATH` environment variable, too.

1.3.2 Kernel operation

The communication between the Jupyter frontend and GAP happens through ZeroMQ streams as documented here, encoded as JSON dicts. After entering code into a cell and instructing Jupyter to execute that code, the jupyter frontend sends the code to the GAP session where it is executed by using the GAP function `READ_ALL_COMMANDS`, resulting values of the execution are rendered using `ViewString` and sent back to the Jupyter frontend. In principle, rich rendering of content, as exemplified in the function `JUPYTER_DotSplash` is possible. Tab-completion is handled by the GAP function `JUPYTER_completion`, and inspection is handled by `JUPYTER_Inspect`. Changing these functions, one can change the behaviour of Tab-completion and inspection to improve user experience.

1.4 Known Limitations and Caveats

Currently the support of the GAP system for alternative frontends is a work in progress. In particular, certain outputs that are printed by GAP cannot be captured by the Jupyter frontend and will not show up. If you happen to notice problems of this kind, feel free to report them on the issue tracker or suggest a solution via a pull-request.

1.5 Feedback

For bug reports, feature requests and suggestions, please use our issue tracker.
Chapter 2

Jupyter Kernel

A Jupyter Kernel is an object that can handle the Jupyter Protocol.

2.1 Functions

2.1.1 JUPYTER_LogProtocol

> JUPYTER_LogProtocol(filename) (function)

Opens a file that is used to log all Jupyter protocol messages.

2.1.2 JUPYTER_UnlogProtocol

> JUPYTER_UnlogProtocol(arg) (function)

Closes the protocol log.
Chapter 3

Jupyter Renderables

A JupyterRenderable is an object that can be rendered by Jupyter. JupyterRenderables are component objects that have to contain at least the components data and metadata.

These components are themselves GAP records which can contain different representations of an object to be rendered. The record component name is the MIME-Type of the representation and the content is the representation itself.

Example

```galois
render := JupyterRenderable(
    rec( text/plain := "Integers",
        text/html := "$\mathbb{Z}$" ),
    rec( ) );
render2 := JupyterRenderable(
    rec( ("image/svg+xml") := "<svg></svg>"
        , rec( ("image/svg+xml") := rec( width := 500, height := 500 ) ) );
```

3.1 Handlers for Jupyter requests

3.1.1 IsJupyterRenderable (for IsObject)

> IsJupyterRenderable(arg) (filter)

Returns: true or false
JupyterRenderable

3.1.2 (for IsComponentObjectRep and IsJupyterRenderable)

> (arg) (filter)

Returns: true or false

3.1.3 JupyterRenderable (for IsObject, IsObject)

> JupyterRenderable(data, metadata) (operation)

Returns: A new JupyterRenderable
Basic constructor for JupyterRenderable
3.1.4 **JupyterRender (for IsObject)**

▷ JupyterRender(arg) (operation)

Method that provides rich viewing experience if code used inside Jupyter

3.1.5 **JupyterRenderableData (for IsJupyterRenderable)**

▷ JupyterRenderableData(arg) (attribute)

Accessor for data in a JupyterRenderable

3.1.6 **JupyterRenderableMetadata (for IsJupyterRenderable)**

▷ JupyterRenderableMetadata(arg) (attribute)

Accessor for metadata in a JupyterRenderable
Chapter 4

Jupyter Utility Functions

4.1 Functions

4.1.1 JUPYTER_print

$\texttt{JUPYTER\_print(arg)}$  

Jupyter printing

4.1.2 JUPYTER_Complete

$\texttt{JUPYTER\_Complete(arg)}$  

This function is called when the user presses Tab in a code cell and produces a list of possible completions. It is passed the current code in the cell, and the curser position inside the code.

4.2 Additional Utility Functions

4.2.1 ISO8601Stamp

$\texttt{ISO8601Stamp(arg)}$  

Current date and time as ISO8601 timestamp. Don’t trust this function.
